

```
1 // LECTURE 15: Template Literals
2 // The traditional method
3 const firstName = "Jonathan", job =
  • "unemployed", birthYear = 2001;
4 const jonathan = "I'm " + firstName + ", "
  • + job + ", age " + (2021 - birthYear); /
  • / see the operator precedence, we are
  • forcing the compiler to do the
  • subtraction before the concatenation.
5 // Also how does this work in JS since
  • 2021 - birthYear is a number? This is
  • something called "Type Coersion" - but
  • JS will automatically convert this
  • number into a string and THEN output it
  • to the console.
6 console.log(jonathan);
7
8 // Using template literals for strings
9 // Can assemble multiple pieces into 1
  • final strings
10 // Template literals use backticks ``
11 const newJon = `I'm ${firstName}, ${job},
  • age ${2021-birthYear}`; // new ES6
  • feature!!
12 console.log(newJon);
13 // We can use backticks for any regular
  • string
14 console.log(`Just a normal string!`);
15
16 // Creating multiline strings
17 console.log('String with \n\
18 multiple lines \n\
```

```
19 lines'); // JavaScript ES5
20 //With template strings:
21 console.log(`string with
22 Multiple
23 Lines`); // you don't need to put \n\
  • anymore!!
24
```
